(54) Title: OLIGONUCLEOTIDE MODULATION OF CELL ADHESION

(57) Abstract

Compositions and methods are provided for the treatment and diagnosis of diseases amenable to treatment through modulation of the synthesis or metabolism of intercellular adhesion molecules. In accordance with preferred embodiments, oligonucleotides and oligonucleotide analogs are provided which are specifically hybridizable with nucleic acids encoding intercellular adhesion molecule-1, vascular cell adhesion molecule-1, and endothelial leukocyte adhesion molecule-1. The oligonucleotide comprises nucleotide units sufficient in identity and number to effect said specific hybridization. In other preferred embodiments, the oligonucleotides are specifically hybridizable with a transcription initiation site, a translation initiation site, 5'-untranslated sequences, 3'-untranslated sequences, and intervening sequences. Methods of treating animals suffering from disease amenable to therapeutic intervention by modulating cell adhesion proteins with an oligonucleotide or oligonucleotide analog specifically hybridizable with RNA or DNA corresponding to one of the foregoing proteins are disclosed. Methods for treatment of diseases responding to modulation cell adhesion molecules are disclosed.

- 1 -

OLIGONUCLEOTIDE MODULATION OF CELL ADHESION

FIELD OF THE INVENTION

This invention relates to diagnostics, research
reagents, and therapies for disease states which respond to
5   modulation of the synthesis or metabolism of cell adhesion
molecules. In particular, this invention relates to
antisense oligonucleotide interactions with certain
messenger ribonucleic acids (mRNAs) or DNAs involved in the
synthesis of proteins that regulate adhesion of white blood
10 cells to other white blood cells and to other cell types.
Antisense oligonucleotides designed to hybridize to the
mRNA encoding intercellular adhesion molecule-1 (ICAM-1),
endothelial leukocyte adhesion molecule-1 (ELAM-1), and
vascular cell adhesion molecule-1 (VCAM-1) are provided.
15 These oligonucleotides have been found to lead to the
modulation of the activity of the RNA or DNA, and thus to
the modulation of the synthesis and metabolism of specific
cell adhesion molecules. Palliation and therapeutic effect
result.

20 ### BACKGROUND OF THE INVENTION

Inflammation is a localized protective response
elicited by tissues in response to injury, infection, or
tissue destruction resulting in the destruction of the
infectious or injurious agent and isolation of the injured
25 tissue. A typical inflammatory response proceeds as
follows: recognition of an antigen as foreign or
recognition of tissue damage, synthesis and release of
soluble inflammatory mediators, recruitment of inflammatory
cells to the site of infection or tissue damage,

- 2 -

destruction and removal of the invading organism or damaged
tissue, and deactivation of the system once the invading
organism or damage has been resolved. In many human
diseases with an inflammatory component, the normal,
5   homeostatic mechanisms which attenuate the inflammatory
responses are defective, resulting in damage and
destruction of normal tissue.

Cell-cell interactions are involved in the
activation of the immune response at each of the stages
10 described above. One of the earliest detectable events in
a normal inflammatory response is adhesion of leukocytes to
the vascular endothelium, followed by migration of
leukocytes out of the vasculature to the site of infection
or injury. The adhesion of these leukocytes, or white
15 blood cells, to vascular endothelium is an obligate step in
the migration out of the vasculature. Harlan, J.M., *Blood*
65: 513-525 (1985). In general, the first inflammatory
cells to appear at the site of inflammation are neutrophils
followed by monocytes, and lymphocytes. Cell-cell
20 interactions are also critical for propagation of both B-
lymphocytes and T-lymphocytes resulting in enhanced humoral
and cellular immune responses, respectively.

The adhesion of white blood cells to vascular
endothelium and other cell types is mediated by
25 interactions between specific proteins, termed "adhesion
molecules," located on the plasma membrane of both white
blood cells and vascular endothelium. The interaction
between adhesion molecules is similar to classical receptor
ligand interactions with the exception that the ligand is
30 fixed to the surface of a cell instead of being soluble.
The identification of patients with a genetic defect in
leukocyte adhesion has enabled investigators to identify a
family of proteins responsible for adherence of white blood
cells. Leukocyte adhesion deficiency (LAD) is a rare
35 autosomal trait characterized by recurrent bacterial
infections and impaired pus formation and wound healing.
The defect was shown to occur in the common B-subunit of

- 3 -

three heterodimeric glycoproteins, Mac-1, LFA-1, and
p150,95, normally expressed on the outer cell membrane of
white blood cells. Anderson and Springer, *Ann. Rev. Med.*
38:175-194 (1987). Patients suffering from LAD exhibit a
5   defect in a wide spectrum of adherence-dependent functions
of granulocytes, monocytes, and lymphocytes. Two ligands
for LFA-1 have been identified, intercellular adhesion
molecules 1 and 2 (ICAM-1 and ICAM-2). Both Mac-1 and
p150,95 bind complement fragment C3bi and perhaps other
10   unidentified ligands.

Other adhesion molecules have been identified
which are involved in the adherence of white blood cells to
vascular endothelium and subsequent migration out of the
vasculature. These include endothelial leukocyte adhesion
15   molecule-1 (ELAM-1), vascular cell adhesion molecule-1
(VCAM-1) and granule membrane protein-140 (GMP-140) and
their respective receptors. The adherence of white blood
cells to vascular endothelium appears to be mediated in
part if not *in toto* by the five cell adhesion molecules
20   ICAM-1, ICAM-2, ELAM-1, VCAM-1 and GMP-140. Dustin and
Springer, *J. Cell Biol.*, 107:321-331 (1987). Expression on
the cell surface of ICAM-1, ELAM-1, VCAM-1 and GMP-140
adhesion molecules is induced by inflammatory stimuli. In
contrast, expression of ICAM-2 appears to be constitutive
25   and not sensitive to induction by cytokines. In general,
GMP-140 is induced by autocoids such as histamine,
leukotriene B_4, platelet activating factor, and thrombin.
Maximal expression on endothelial cells is observed 30
minutes to 1 hour after stimulation and returns to baseline
30   within 2 to 3 hours. The expression of ELAM-1 and VCAM-1
on endothelial cells is induced by cytokines such as
interleukin-1ß and tumor necrosis factor, but not gamma-
interferon. Maximal expression of ELAM-1 on the surface
of endothelial cells occurs 4 to 6 hours after stimulation
35   and returns to baseline by 16 hours. ELAM-1 expression is
dependent on new mRNA and protein synthesis. Elevated
VCAM-1 expression is detectable 2 hours following treatment

- 4 -

with tumor necrosis factor, is maximal 8 hours following stimulation, and remains elevated for at least 48 hours following stimulation. Rice and Bevilacqua, *Science*, 246:1303-1306 (1989). ICAM-1 expression on endothelial

5 cells is induced by cytokines interleukin-1 tumor necrosis factor and gamma-interferon. Maximal expression of ICAM-1 follows that of ELAM-1 occurring 8 to 10 hours after stimulation and remains elevated for at least 48 hours.

GMP-140 and ELAM-1 are primarily involved in the

10 adhesion of neutrophils to vascular endothelial cells. VCAM-1 primarily binds T and B lymphocytes. In addition, VCAM-1 may play a role in the metastasis of melanoma, and possibly other cancers. ICAM-1 plays a role in adhesion of neutrophils to vascular endothelium, as well as adhesion of

15 monocytes and lymphocytes to vascular endothelium, tissue fibroblasts and epidermal keratinocytes. ICAM-1 also plays a role in T-cell recognition of antigen presenting cell, lysis of target cells by natural killer cells, lymphocyte activation and proliferation, and maturation of T cells in

20 the thymus. In addition, recent data have demonstrated that ICAM-1 is the cellular receptor for the major serotype of rhinovirus, which account for greater than 50% of common colds. Staunton et al., *Cell*, 56: 849-853 (1989); Greve et al., *Cell*, 56: 839-847 (1989).

25 Expression of ICAM-1 has been associated with a variety of inflammatory skin disorders such as allergic contact dermatitis, fixed drug eruption, lichen planus, and psoriasis; Ho et al., *J. Am. Acad. Dermatol.*, 22: 64-68 (1990); Griffiths and Nickoloff, *Am. J. Pathology*, 135:

30 1045-1053 (1989); Lisby et al., *Br. J. Dermatol.*, 120:479-484 (1989); Shiohara et al., *Arch. Dermatol.*, 125: 1371-1376 (1989). In addition, ICAM-1 expression has been detected in the synovium of patients with rheumatoid arthritis; Hale et al., *Arth. Rheum.*, 32: 22-30 (1989),

35 pancreatic B-cells in diabetes; Campbell et al., *Proc. Natl. Acad. Sci. U.S.A.*, 86:4282-4286 (1989); thyroid follicular cells in patients with Graves' disease; Weetman

- 5 -

et al., *J. Endocrinol.*, 122: 185-191 (1989); and with renal and liver allograft rejection; Faull and Russ, *Transplantation*, 48: 226-230 (1989); Adams et al., *Lancet*, 1122-1125 (1989).

5   It is has been hoped that inhibitors of ICAM-1, VCAM-1 and ELAM-1 expression would provide a novel therapeutic class of anti-inflammatory agents with activity towards a variety of inflammatory diseases or diseases with an inflammatory component such as asthma, rheumatoid

10   arthritis, allograft rejections, various dermatological conditions, and psoriasis. In addition, inhibitors of ICAM-1, VCAM-1, and ELAM-1 may also be effective in the treatment of colds due to rhinovirus infection, AIDS, and some cancers and their metastasis. To date, there are no

15   known therapeutic agents which effectively prevent the expression of the cellular adhesion molecules ELAM-1, VCAM-1 and ICAM-1. The use of neutralizing monoclonal antibodies against ICAM-1 in animal models provide evidence that such inhibitors if identified would have therapeutic

20   benefit for asthma; Wegner et al., *Science*, 247:456-459 (1990) and renal allografts; Cosimi et al., *J. Immunol.*, 144:4604-4612 (1990). The use of a soluble form of ICAM-1 molecule was also effective in preventing rhinovirus infection of cells in culture. Marlin et al., *Nature*,

25   344:70-72 (1990).
        Current agents which affect intercellular adhesion molecules include synthetic peptides, monoclonal antibodies, and soluble forms of the adhesion molecules. To date, synthetic peptides which block the interactions

30   with ICAM-1, VCAM-1 or ELAM-1 have not been identified. Monoclonal antibodies may prove to be useful for the treatment of acute inflammatory response due to expression of ICAM-1, VCAM-1 and ELAM-1. However, with chronic treatment, the host animal develops antibodies against the

35   monoclonal antibodies thereby limiting their usefulness. In addition, monoclonal antibodies are large proteins which may have difficulty in gaining access to the inflammatory

- 6 -

site. Soluble forms of the cell adhesion molecules suffer
from many of the same limitations as monoclonal antibodies
in addition to the expense of their production. Thus,
there is a long felt need for molecules which effectively
5   inhibit intercellular adhesion molecules. Antisense
oligonucleotides avoid many of the pitfalls of current
agents used to block the effects of ICAM-1, VCAM-1 and
ELAM-1.

       PCT/US90/02357 (Hession et al.) discloses DNA
10   sequences encoding Endothelial Adhesion Molecules (ELAMs),
including ELAM-1 and VCAM-1 and VCAM-1b. A number of uses
for these DNA sequences are provided, including (1)
production of monoclonal antibody preparations that are
reactive for these molecules which may be used as
15   therapeutic agents to inhibit leukocyte binding to
endothelial cells; (2) production of ELAM peptides to bind
to the ELAM ligand on leukocytes which, in turn, may bind
to ELAM on endothelial cells, inhibiting leukocyte binding
to endothelial cells; (3) use of molecules binding to ELAMS
20   (such as anti-ELAM antibodies, or markers such as the
ligand or fragments of it) to detect inflammation; (4) use
of ELAM and ELAM ligand DNA sequences to produce nucleic
acid molecules that intervene in ELAM or ELAM ligand
expression at the translational level using antisense
25   nucleic acid and ribozymes to block translation of a
specific mRNA either by masking mRNA with antisense nucleic
acid or cleaving it with a ribozyme. It is disclosed that
coding regions are the targets of choice. For VCAM-1, AUG
is believed to be most likely; a 15-mer hybridizing to the
30   AUG site is specifically disclosed in Example 17.
OBJECTS OF THE INVENTION
       It is a principle object of the invention to
provide therapies for diseases with an immunological
component, allografts, cancers and metastasis, colds, and
35   AIDS through perturbation in the synthesis and expression
of inflammatory cell adhesion molecules.

It is a further object of the invention to provide antisense oligonucleotides or oligonucleotide analogs which are capable of inhibiting the function of nucleic acids encoding intercellular adhesion proteins.

5   Yet another object is to provide means for diagnosis of dysfunctions of intercellular adhesion.

These and other objects of this invention will become apparent from a review of the instant specification.

SUMMARY OF THE INVENTION

In accordance with the present invention, oligonucleotides and oligonucleotide analogs are provided which specifically hybridize with nucleic acids encoding intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1) and endothelial leukocyte adhesion molecule-1 (ELAM-1). The oligonucleotides and oligonucleotide analogs are designed to bind either directly to mRNA or to a selected DNA portion forming a triple stranded structure, thereby modulating the amount of mRNA made from the gene.

The former relationship is commonly denoted as "antisense." The oligonucleotides and oligonucleotide analogs are able to inhibit the function of RNA or DNA, either its translation into protein, its translocation into the cytoplasm, or any other activity necessary to its overall biological function. The failure of the RNA or DNA to perform all or part of its function results in failure of a portion of the genome controlling cell adhesion molecules to be properly expressed, thus modulating said metabolism.

- 9 -

It is preferred to target specific genes for antisense attack. It has been discovered that the genes coding for ICAM-1, VCAM-1 and ELAM-1 are particularly useful for this approach. Inhibition of ICAM-1, VCAM-1 and
5   ELAM-1 expression is expected to be useful for the treatment of inflammatory diseases, diseases with an inflammatory component, allografts, cancers and their metastasis, and viral infections.

Methods of modulating cell adhesion comprising
10   contacting the animal with an oligonucleotide or oligonucleotide analog hybridizable with nucleic acids encoding a protein capable of modulating cell adhesion are provided. Oligonucleotides or oligonucleotide analogs hybridizable with an RNA or DNA encoding ICAM-1, VCAM-1 and
15   ELAM-1 are preferred. Methods for diagnosis are also a part of this invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Antisense oligonucleotides hold great promise as therapeutic agents for the treatment of many human
20   diseases. Conceptually, it is much easier to design compounds which interact with a primary structure of a molecule such as an RNA molecule by base pairing than it is to design a molecule to interact with the active site of an enzyme or ligand binding site of a receptor.
25   Oligonucleotides specifically bind to the complementary sequence of either pre-mRNA or mature mRNA, as defined by Watson-Crick base pairing, inhibiting the flow of genetic information from DNA to protein. The properties of antisense oligonucleotides which make them specific for
30   their target sequence also make them extraordinarily versatile. Because antisense oligonucleotides are long chains of four monomeric units they may be readily synthesized for any target RNA sequence. Numerous recent studies have documented the utility of antisense
35   oligonucleotides as biochemical tools for studying target proteins. Rothenberg et al., *J. Natl. Cancer Inst.*, 81:1539-1544 (1989); Zon, G. *Pharmaceutical Res.*, 5:539-

549). Because of recent advances in oligonucleotide chemistry, synthesis of nuclease resistant oligonucleotides, and oligonucleotide analogs which exhibit enhanced cell uptake, it is now possible to consider the

5 use of antisense oligonucleotides as a novel form of therapeutics.

Antisense oligonucleotides offer an ideal solution to the problems encountered in prior art approaches. They can be designed to selectively inhibit a

10 given isoenzyme, they inhibit the production of the enzyme, and they avoid non-specific mechanisms such as free radical scavenging or binding to multiple receptors. A complete understanding of enzyme mechanisms or receptor-ligand interactions is not needed to design specific inhibitors.

15 **DESCRIPTION OF TARGETS**

The acute infiltration of neutrophils into the site of inflammation appears to be due to increased expression of GMP-140, ELAM-1 and ICAM-1 on the surface of endothelial cells. The appearance of lymphocytes and

20 monocytes during the later stages of an inflammatory reaction appear to be mediated by VCAM-1 and ICAM-1. ELAM-1 and GMP-140 are transiently expressed on vascular endothelial cells, while VCAM-1 and ICAM-1 are chronically expressed.

25 Human ICAM-1 is encoded by a 3.3-kb mRNA resulting in the synthesis of a 55,219 dalton protein (Figure 1). ICAM-1 is heavily glycosylated through N-linked glycosylation sites. The mature protein has an apparent molecular mass of 90 kDa as determined by SDS-

30 polyacrylamide gel electrophoresis. Staunton et al., *Cell*, 52:925-933. ICAM-1 is a member of the immunoglobulin supergene family, containing 5 immunoglobulin-like domains at the amino terminus, followed by a transmembrane domain and a cytoplasmic domain. The primary binding site for

35 LFA-1 and rhinovirus are found in the first immunoglobulin-like domain. However, the binding sites appear to be distinct. Staunton et al., *Cell*, 61:243-354 (1990).

- 11 -

Recent electron micrographic studies demonstrate that ICAM-1 is a bent rod 18.7 nm in length and 2 to 3 nm in diameter. Staunton et al., *Cell*, 61:243-254 (1990).

ICAM-1 exhibits a broad tissue and cell
5 distribution, and may be found on white blood cells, endothelial cells, fibroblast, keratinocytes and other epithelial cells. The expression of ICAM-1 can be regulated on vascular endothelial cells, fibroblasts, keratinocytes, astrocytes and several cell lines by
10 treatment with bacterial lipopolysaccharide and cytokines such as interleukin-1, tumor necrosis factor, gamma-interferon, and lymphotoxin. *See, e.g.*, Frohman, et al., *J. Neuroimmunol.*, 23:117-124 (1989). The molecular mechanism for increased expression of ICAM-1 following
15 cytokine treatment has not been determined.

ELAM-1 is a 115-kDa membrane glycoprotein (Figure 2) which is a member of the selectrin family of membrane glycoproteins. Bevilacqua et al., *Science*, 243:1160-1165 (1989). The amino terminal region of ELAM-1 contains
20 sequences with homologies to members of lectin-like proteins, followed by a domain similar to epidermal growth factor, followed by six tandem 60-amino acid repeats similar to those found in complement receptors 1 and 2. These features are also shared by GMP-140 and MEL-14
25 antigen, a lymphocyte homing antigen. ELAM-1 is encoded for by a 3.9-kb mRNA. The 3'-untranslated region of ELAM-1 mRNA contains several sequence motifs ATTTA which are responsible for the rapid turnover of cellular mRNA consistent with the transient nature of ELAM-1 expression.
30 ELAM-1 exhibits a limited cellular distribution in that it has only been identified on vascular endothelial cells. Like ICAM-1, ELAM-1 is inducible by a number of cytokines including tumor necrosis factor, interleukin-1 and lymphotoxin and bacterial lipopolysaccharide. In
35 contrast to ICAM-1, ELAM-1 is not induced by gamma-interferon. Bevilacqua et al., *Proc. Natl. Acad. Sci. USA*, 84:9238-9242 (1987); Wellicome et al., *J. Immunol.*,

- 12 -

144:2558-2565 (1990). The kinetics of ELAM-1 mRNA
induction and disappearance in human umbilical vein
endothelial cells precedes the appearance and disappearance
of ELAM-1 on the cell surface. As with ICAM-1 the
5   molecular mechanism for ELAM-1 induction is not known.

VCAM-1 is a 110-kDa membrane glycoprotein encoded
by a 3.2-kb mRNA (Figure 3). VCAM-1 appears to be encoded
by a single-copy gene. Osborn et al., *Cell*, 59:1203-1211
(1989). Like ICAM-1, VCAM-1 is a member of the
10   immunoglobulin supergene family, containing six
immunoglobulin-like domains of the H type. The receptor
for VCAM-1 is proposed to be CD29 as demonstrated by the
ability of monoclonal antibodies to CD29 to block adherence
of Ramos cells to VCAM-1. VCAM-1 is expressed primarily on
15   vascular endothelial cells. Like ICAM-1 and ELAM-1,
expression of VCAM-1 on vascular endothelium is regulated
by treatment with cytokines. Rice and Bevilacqua, *Science*,
246: 1303-1306 (1989); Rice et al., *J. Exp. Med.*, 171:1369-
1374 (1990). Increased expression appears to be due to
20   induction of the mRNA.

For therapeutics, an animal suspected of having a
disease which can be treated by decreasing the expression
of ICAM-1, VCAM-1 and ELAM-1 is treated by administering
oligonucleotides or oligonucleotide analogs in accordance
25   with this invention. Persons of ordinary skill can easily
determine optimum dosages, dosing methodologies and
repetition rates. Such treatment is generally continued
until either a cure is effected or a diminution in the
disease state is achieved. Long term treatment is likely
30   for some diseases.

The present invention employs oligonucleotides
and oligonucleotide analogs for use in antisense inhibition
of the function of RNA and DNA corresponding to proteins
capable of modulating inflammatory cell adhesion. In the
35   context of this invention, the term "oligonucleotide"
refers to a polynucleotide formed from naturally occurring
bases and furanosyl groups joined by native phosphodiester

- 13 -

bonds.   This term effectively refers to naturally occurring
species or synthetic species formed from naturally
occurring subunits or their close homologs.

"Oligonucleotide analog," as that term is used in
5   connection with this invention, refers to moieties which
function similarly to oligonucleotides but which have non-
naturally occurring portions.   Thus, oligonucleotide
analogs may have altered sugar moieties or inter-sugar
linkages.   Exemplary among these are the phosphorothioate
10   and other sulfur-containing species which are known for use
in the art.   In accordance with some preferred embodiments,
at least some of the phosphodiester bonds of the
oligonucleotide have been substituted with a structure
which functions to enhance the ability of the compositions
15   to penetrate into the region of cells where the RNA or DNA
whose activity to be modulated is located.   It is preferred
that such substitutions comprise phosphorothioate bonds,
methyl phosphonate bonds, or short chain alkyl or
cycloalkyl structures.   In accordance with other preferred
20   embodiments, the phosphodiester bonds are substituted with
other structures which are, at once, substantially non-
ionic and non-chiral, or with structures which are chiral
and enantiomerically specific.   Persons of ordinary skill
in the art will be able to select other linkages for use in
25   practice of the invention.

Oligonucleotide analogs may also include species
which include at least some modified base forms.   Thus,
purines and pyrimidines other than those normally found in
nature may be so employed.   Similarly, modifications on the
30   furanosyl portions of the nucleotide subunits may also
occur as long as the essential tenets of this invention are
adhered to.   Examples of such modifications are 2'-O-alkyl-
and 2'-halogen-substituted nucleotides.

Such analogs are best described as being
35   functionally interchangeable with natural oligonucleotides
(or oligonucleotides synthesized along natural lines), but
which have one or more differences from natural structure.

All such analogs are comprehended by this invention so long
as they function effectively to hybridize with RNA and DNA
deriving from a gene corresponding to one of the proteins
capable of modulating intercellular adhesion. The
5   oligonucleotides and oligonucleotide analogs in accordance
with this invention preferably comprise from about 3 to
about 50 subunits. It is more preferred that such
oligonucleotides and oligonucleotide analogs comprise from
about 8 to 25 subunits, and still more preferred to have
10   from about 12 to 22 subunits. As will be appreciated, a
subunit is a base-sugar combination suitably bound to
adjacent subunits through phosphodiester or other bonds.

      The oligonucleotides and oligonucleotide analogs
used in accordance with this invention may be conveniently
15   and routinely made through the well-known technique of
solid phase synthesis. Equipment for such synthesis is
sold by several vendors including Applied Biosystems. Any
other means for such synthesis may also be employed,
however the actual synthesis of the oligonucleotides is
20   well within the talents of the routineer. It is also well
known to use similar techniques to prepare other
oligonucleotide analogs such as the phosphorothioates and
alkylated derivatives.

      In accordance with this invention, persons of
25   ordinary skill in the art will understand that messenger
RNA identified by the open reading frames (ORFs) of the DNA
from which they are transcribed includes not only the
information from the ORFs of the DNA, but also associated
ribonucleotides which form regions known to such persons as
30   the 5'-untranslated region, the 3'- untranslated region,
and intervening sequence ribonucleotides. Thus,
oligonucleotides and oligonucleotide analogs may be
formulated in accordance with this invention which are
targeted wholly or in part to these associated
35   ribonucleotides as well as to the informational
ribonucleotides. In preferred embodiments, the
oligonucleotide or oligonucleotide analog is specifically

- 15 -

hybridizable with a transcription initiation site, a
translation initiation site, an intervening sequence and
sequences in the 3'-untranslated region.

5   In accordance with this invention, the
oligonucleotide is specifically hybridizable with portions
of nucleic acids encoding a protein involved in the
adhesion of white blood cells either to other white blood
cells or other cell types. In preferred embodiments, said
proteins are intercellular adhesion molecule-1, vascular

10 cell adhesion molecule-1 and endothelial leukocyte adhesion
molecule-1. Oligonucleotides or analogs comprising the
corresponding sequence, or part thereof, are useful in the
invention. For example, Figure 1 is a human intercellular
adhesion molecule-1 mRNA sequence. A preferred sequence

15 segment which may be useful in whole or in part is:

            5'   3'

           TGGGAGCCATAGCGAGGC
           GAGGAGCTCAGCGTCGACTG
           GACACTCAATAAATAGCTGGT

20   GAGGCTGAGGTGGGAGGA
           CGATGGGCAGTGGGAAAG
           GGGCGCGTGATCCTTATAGC

While the illustrated sequences are believed to
be accurate, the present invention is directed to the
20   correct sequences should errors be found. Oligonucleotides
or analogs useful in the invention comprise one of these
sequences, or part thereof. Thus, it is preferred to
employ any of these oligonucleotides (or their analogs) as
set forth above or any of the similar oligonucleotides or
25   oligonucleotide analogs which persons of ordinary skill in
the art can prepare from knowledge of the preferred
antisense targets for the modulation of the synthesis of
inflammatory cell adhesion molecules.

Several preferred embodiments of this invention
30   are exemplified in accordance with the following
nonlimiting examples. The target mRNA species for
modulation relates to intercellular adhesion molecule-1,
endothelial leukocyte adhesion molecule-1, and vascular
cell adhesion molecule-1. Persons of ordinary skill in the
35   art will appreciate that the present invention is not so
limited, however, and that it is generally applicable. The
inhibition or modulation of production of the ICAM-1 and/or

- 17 -

ELAM-1 and/or VCAM-1 are expected to have significant
therapeutic benefits in the treatment of disease. In order
to assess the effectiveness of the compositions, an assay
or series of assays is required.

5   **EXAMPLES**

EXAMPLE 1

Expression of ICAM-1, VCAM-1 and ELAM-1 on the
surface of cells can be quantitated using specific
monoclonal antibodies in an ELISA. Cells are grown to
10   confluence in 96 well microtiter plates. The cells are
stimulated with either interleukin-1 or tumor necrosis
factor for 4 to 8 hours to quantitate ELAM-1 and 8 to 24
hours to quantitate ICAM-1 and VCAM-1. Following the
appropriate incubation time with the cytokine, the cells
15   are gently washed three times with a buffered isotonic
solution containing calcium and magnesium such as
Dulbecco's phosphate buffered saline (D-PBS). The cells
are then directly fixed on the microtiter plate with 1 to
2% paraformaldehyde diluted in D-PBS for 20 minutes at 25°
20   C. The cells are washed again with D-PBS three times.
Nonspecific binding sites on the microtiter plate are
blocked with 2% bovine serum albumin in D-PBS for 1 hour at
37° C. Cells are incubated with the appropriate monoclonal
antibody diluted in blocking solution for 1 hour at 37°C.
25   Unbound antibody is removed by washing the cells three
times with D-PBS. Antibody bound to the cells is detected
by incubation with a 1:1000 dilution of biotinylated goat
anti-mouse IgG (Bethesda Research Laboratories,
Gaithersberg, MD) in blocking solution for 1 hour at 37°C.
30   Cells are washed three times with D-PBS and then incubated
with a 1:1000 dilution of streptavidin conjugated to ß-
galactosidase (Bethesda Research Laboratories) for 1 hour
at 37°C. The cells are washed three times with D-PBS for 5
minutes each. The amount of ß-galactosidase bound to the
35   specific monoclonal antibody is determined by developing
the plate in a solution of 3.3 mM chlorophenolred-ß-D-
galactopyranoside, 50 mM sodium phosphate, 1.5 mM $MgCl_2$;

pH=7.2 for 2 to 15 minutes at 37°C. The concentration of
the product is determined by measuring the absorbance at
575 nm in an ELISA microtiter plate reader.

5   An example of the induction of ICAM-1 observed
following stimulation with either interleukin-1ß or tumour
necrosis factor α in several human cell lines is shown in
Figure 4. Cells were stimulated with increasing
concentrations of interleukin-1 or tumour necrosis factor
for 15 hours and processed as described above. ICAM-1

10   expression was determined by incubation with a 1:1000
dilution of the monoclonal antibody 84H10 (Amac Inc.,
Westbrook, ME). The cell lines used were passage 4 human
umbilical vein endothelial cells (HUVEC), a human epidermal
carcinoma cell line (A431), a human melanoma cell line (SK-

15   MEL-2) and a human lung carcinoma cell line (A549). ICAM-
1 was induced on all the cell lines, however, tumor
necrosis factor was more effective than interleukin-1 in
induction of ICAM-1 expression on the cell surface (Figure
4).

20   Screening antisense oligonucleotides for
inhibition of ICAM-1, VCAM-1 or ELAM-1 expression is
performed as described above with the exception of
pretreatment of cells with the oligonucleotides prior to
challenge with the cytokines. An example of antisense

25   oligonucleotide inhibition of ICAM-1 expression is shown in
Figure 5. Human umbilical vein endothelial cells (HUVEC)
were treated with increasing concentration of
oligonucleotide diluted in Opti MEM (GIBCO, Grand Island,
NY) containing 16 μM N-[1-(2,3-dioleyloxy) propyl]-N,N,N-

30   trimethylammonium chloride (DOTMA) for 4 hours at 37°C to
enhance uptake of the oligonucleotides. The medium was
removed and replaced with endothelial growth medium (EGM-
UV; Clonetics, San Diego, CA) containing the indicated
concentration of oligonucleotide for an additional 4 hours.

35   Interleukin- 1ß was added to the cells at a concentration
of 5 units/ml and incubated for 14 hours at 37°C. The cells
were quantitated for ICAM-1 expression using a 1:1000

- 19 -

dilution of the monoclonal antibody 84H10 as described
above. The oligonucleotides used were:

COMPOUND 1 - (ISIS 1558) a phosphodiester
oligonucleotide designed to hybridize with position 64-80
5   of the mRNA covering the AUG initiation of translation
codon having the sequence

5'-TGGGAGCCATAGCGAGGC-3'.

COMPOUND 2 - (ISIS 1570) a phosphorothioate
containing oligonucleotide corresponding to the same
10   sequence as COMPOUND 1.

COMPOUND 3 - a phosphorothioate oligonucleotide
complementary to COMPOUND 1 and COMPOUND 2 exhibiting the
sequence

5'-GCCTCGCTATGGCTCCCA-3'.

15   COMPOUND 4 - (ISIS 1572) a phosphorothioate
containing oligonucleotide designed to hybridize to
positions 2190-2210 of the mRNA in the 3'untranslated
region containing the sequence

5'-GACACTCAATAAATAGCTGGT-3'.

20   COMPOUND 5 - (ISIS 1821) a phosphorothioate
containing oligonucleotide design to hybridize to human 5-
lipoxygenase mRNA used as a control containing the sequence

5'-CATGGCGCGGGCCGCGGG-3'.

The phosphodiester oligonucleotide targeting the
25   AUG initiation of translation region of the human ICAM-1
mRNA (COMPOUND 1) failed to inhibit expression of ICAM-1,
however, the corresponding phosphorothioate containing
oligonucleotide (COMPOUND 2) inhibited ICAM-1 expression by
70% at a concentration of 0.1 μM and 90% at 1 μM
30   concentration (Figure 4). The increased potency of the
phosphorothioate oligonucleotide over the phosphodiester is
probably due to increased stability. The sense strand to
COMPOUND 2, COMPOUND 3, modestly inhibited ICAM-1
expression at 10 μM. If COMPOUND 2 was prehybridized to
35   COMPOUND 3 prior to addition to the cells, the effects of
COMPOUND 2 on ICAM-1 expression were attenuated suggesting
that the activity of COMPOUND 2 was due to antisense

- 20 -

oligonucleotide effect, requiring hybridization to the mRNA. The antisense oligonucleotide directed against 3' untranslated sequences (COMPOUND 4) inhibited ICAM-1 expression 62% at a concentration of 1 μM (Figure 5). The

5 control oligonucleotide, targeting human 5-lipoxygenase (COMPOUND 5) reduced ICAM-1 expression by 20%. These data demonstrate that oligonucleotides are capable of inhibiting ICAM-1 expression on human umbilical vein endothelial cells and suggest that the inhibition of ICAM-1 expression is due

10 to an antisense activity.

The antisense oligonucleotide COMPOUND 2 at a concentration of 1 μM inhibits expression of ICAM-1 on human umbilical vein endothelial cells stimulated with increasing concentrations of tumor necrosis factor and

15 interleukin-1 (Figure 6). These data demonstrate that the effects of COMPOUND 2 are not specific for interleukin-1 stimulation of cells.

Analogous assays can also be used to demonstrate inhibition of ELAM-1 and VCAM-1 expression by antisense

20 oligonucleotides.

EXAMPLE 2

A second cellular assay which can be used to demonstrate the effects of antisense oligonucleotides on ICAM-1, VCAM-1 or ELAM-1 expression is a cell adherence

25 assay. Target cells are grown as a monolayer in a multiwell plate, treated with oligonucleotide followed by cytokine. The adhering cells are then added to the monolayer cells and incubated for 30 to 60 minutes at 37°C and washed to remove nonadhering cells. Cells adhering to

30 the monolayer may be determined either by directly counting the adhering cells or prelabeling the cells with a radioisotope such as ^{51}Cr and quantitating the radioactivity associated with the monolayer as described. Dustin and Springer, *J. Cell Biol.*, 107:321-331 (1988). Antisense

35 oligonucleotides may target either ICAM-1, VCAM-1 or ELAM-1 in the assay.

- 21 -

An example of the effects of antisense
oligonucleotides targeting ICAM-1 mRNA on the adherence of
DMSO differentiated HL-60 cells to tumor necrosis factor
treated human umbilical vein endothelial cells is shown in
5   Figure 7. Human umbilical vein endothelial cells were
grown to 80% confluence in 12 well plates. The cells were
treated with 2 μM oligonucleotide diluted in Opti-MEM
containing 8 μM DOTMA for 4 hours at 37°C. The medium was
removed and replaced with fresh endothelial cell growth
10   medium (EGM-UV) containing 2 μM of the indicated
oligonucleotide and incubated 4 hours at 37°C. Tumor
necrosis factor, 1 ng/ml, was added to cells as indicated
and cells incubated for an additional 19 hours. The cells
were washed once with EGM-UV and 1.6 x 10^6 HL-60 cells
15   differentiated for 4 days with 1.3% DMSO added. The cells
were allowed to attach for 1 hour at 37°C and gently washed
4 times with Dulbecco's phosphate-buffered saline (D-PBS)
warmed to 37°C. Adherent cells were detached from the
monolayer by addition of 0.25 ml of cold (4°C) phosphate-
20   buffered saline containing 5 mM EDTA and incubated on ice
for 5 minutes. The number of cells removed by treatment
with EDTA was determined by counting with a hemocytometer.
Endothelial cells detached from the monolayer by EDTA
treatment could easily be distinguished from HL-60 cells by
25   morphological differences.

In the absence of tumor necrosis factor, 3% of
the HL-60 cells bound to the endothelial cells. Treatment
of the endothelial cell monolayer with 1 ng/ml tumor
necrosis factor increased the number of adhering cells to
30   59% of total cells added (Figure 7). Treatment with the
antisense oligonucleotide COMPOUND 2 or the control
oligonucleotide COMPOUND 5 did not change the number of
cells adhering to the monolayer in the absence of tumor
necrosis factor treatment (Figure 7). The antisense
35   oligonucleotide, COMPOUND 2 reduced the number of adhering
cells from 59% of total cells added to 17% of the total
cells added (Figure 7). In contrast, the control

- 22 -

oligonucleotide COMPOUND 5 did not significantly reduce the
number of cells adhering to the tumor necrosis factor
treated endothelial monolayer, i.e., 53% of total cells
added for COMPOUND 5 treated cells versus 59% for control
5 cells.

These data indicate that antisense
oligonucleotides are capable of inhibiting ICAM-1
expression on endothelial cells and that inhibition of
ICAM-1 expression correlates with a decrease in the
10 adherence of a neutrophil-like cell to the endothelial
monolayer in a sequence specific fashion. Because other
molecules also mediate adherence of white blood cells to
endothelial cells, such as ELAM-1, and VCAM-1 it is not
expected that adherence would be completely blocked.

15 **EXAMPLE 3**

Synthesis and characterization of
<u>oligonucleotides and analogs:</u>

Unmodified DNA oligonucleotides were synthesized
on an automated DNA synthesizer (Applied Biosystems model
20 380B) using standard phosphoramidite chemistry with
oxidation by iodine. ß-cyanoethyldiisopropyl-
phosphoramidites were purchased from Applied Biosystems
(Foster City, CA). For phosphorothioate oligonucleotides,
the standard oxidation bottle was replaced by a 0.2 M
25 solution of 3H-1,2-benzodithiole-3-one 1,1-dioxide in
acetonitrile for the stepwise thiation of the phosphite
linkages. The thiation cycle wait step was increased to 68
seconds and was followed by the capping step.

2'-O-methyl phosphorothioate oligonucleotides
30 were synthesized using 2'-O-methyl ß-cyanoethyldiisopropyl-
phosphoramidites (Chemgenes, Needham MA) and the standard
cycle for unmodified oligonucleotides, except the wait step
after pulse delivery of tetrazole and base was increased to
360 seconds. The 3'-base used to start the synthesis was a
35 2'-deoxyribonucleotide.

2'-fluoro phosphorothioate oligonucleotides were
synthesized using 5'-dimethoxytrityl-3'-phosphoramidites
and prepared as disclosed in U.S. patent application Serial

No. 463,358, filed January 11, 1990, and 566,977, filed
August 13, 1990, which are assigned to the same assignee as
the instant application and which are incorporated by
reference herein. The 2'-fluoro oligonucleotides were
5   prepared using phosphoramidite chemistry and a slight
modification of the standard DNA synthesis protocol:
deprotection was effected using methanolic ammonia at room
temperature.

        After cleavage from the controlled pore glass
10   column (Applied Biosystems) and deblocking in concentrated
ammonium hydroxide at 55°C for 18 hours, the
oligonucleotides were purified by precipitation twice out
of 0.5 M NaCl with 2.5 volumes ethanol. Analytical gel
electrophoresis was accomplished in 20% acrylamide, 8 M
15   urea, 45 mM Tris-borate buffer, pH 7.0.
Oligodeoxynucleotides and their phosphorothioate analogs
were judged from electrophoresis to be greater than 80%
full length material.

        RNA oligonucleotide synthesis was performed on an
20   ABI model 380B DNA synthesizer. The standard synthesis
cycle was modified by increasing the wait step after the
pulse delivery of tetrazole to 900 seconds. The bases were
deprotected by incubation in methanolic ammonia overnight.
Following base deprotections the oligonucleotides were
25   dried *in vacuo*. The t-butyldimethylsilyl protecting the 2'
hydroxyl was removed by incubating the oligonucleotide in 1
M tetrabutylammoniumfluoride in tetrahydrofuran overnight.
The RNA oligonucleotides were further purified on C_{18} Sep-
Pak cartridges (Waters, Division of Millipore Corp.,
30   Milford MA) and ethanol precipitated.

        The relative amounts of phosphorothioate and
phosphodiester linkages obtained by this synthesis were
periodically checked by ^{31}P NMR spectroscopy. The spectra
were obtained at ambient temperature using deuterium oxide
35   or dimethyl sulfoxide-d_6 as solvent. Phosphorothioate
samples typically contained less than one percent of
phosphodiester linkages.

- 24 -

Secondary evaluation was performed with
oligonucleotides purified by trityl-on HPLC on a PRP-1
column (Hamilton Co., Reno, Nevada) using a gradient of
acetonitrile in 50 mM triethylammonium acetate, pH 7.0 (4%
5   to 32% in 30 minutes, flow rate = 1.5 ml/min). Appropriate
fractions were pooled, evaporated and treated with 5%
acetic acid at ambient temperature for 15 minutes. The
solution was extracted with an equal volume of ethyl
acetate, neutralized with ammonium hydroxide, frozen and
10 lyophilized. HPLC-purified oligonucleotides were not
significantly different in potency from precipitated
oligonucleotides, as judged by the ELISA assay for ICAM-1
expression.

EXAMPLE 4

15 Cell culture and treatment with oligonucleotides:

The human lung carcinoma cell line A549 was
obtained from the American Type Culture Collection
(Bethesda MD). Cells were grown in Dulbecco's Modified
Eagle's Medium (Irvine Scientific, Irvine CA) containing 1
20 gm glucose/liter and 10% fetal calf serum (Irvine
Scientific). Human umbilical vein endothelial cells
(HUVEC) (Clonetics, San Diego CA) were cultured in EGM-UV
medium (Clonetics). HUVEC were used between the second and
sixth passages. Human epidermal carcinoma A431 cells were
25 obtained from the American Type Culture Collection and
cultured in DMEM with 4.5 g/l glucose. Primary human
keratinocytes were obtained from Clonetics and grown in KGM
(Keratinocyte growth medium, Clonetics).

Cells grown in 96-well plates were washed three
30 times with Opti-MEM (GIBCO, Grand Island, NY) prewarmed to
37°C. 100 μl of Opti-MEM containing either 10 μg/ml N-[1-
(2,3-dioleyloxy)propyl]-N,N,N-trimethylammonium chloride
(DOTMA, Bethesda Research Labs, Bethesda MD) in the case of
HUVEC cells or 20 μg/ml DOTMA in the case of A549 cells was
35 added to each well. Oligonucleotides were sterilized by
centrifugation through 0.2 μm Centrex cellulose acetate
filters (Schleicher and Schuell, Keene, NH).

Oligonucleotides were added as 20x stock solution to the
wells and incubated for 4 hours at 37°C. Medium was
removed and replaced with 150 μl of the appropriate growth
medium containing the indicated concentration of

5   oligonucleotide. Cells were incubated for an additional 3
to 4 hours at 37°C then stimulated with the appropriate
cytokine for 14 to 16 hours, as indicated. ICAM-1
expression was determined as described in Example 1. The
presence of DOTMA during the first 4 hours incubation with

10   oligonucleotide increased the potency of the
oligonucleotides at least 100-fold. This increase in
potency correlated with an increase in cell uptake of the
oligonucleotide.

EXAMPLE 5

15   ELISA screening of additional antisense oligonucleotides
and oligonucleotide analogs for activity against ICAM-1
gene expression in Interleukin-1ß-stimulated cells:
              Antisense oligonucleotides were originally
designed that would hybridize to five target sites on the

20   human ICAM-1 mRNA. Oligonucleotides were synthesized in
both phosphodiester (P=O; ISIS 1558, 1559, 1563, 1564 and
1565) and phosphorothioate (P=S; ISIS 1570, 1571, 1572,
1573, and 1574) forms. The oligonucleotides and analogs
are shown in Table 1.

25   **TABLE 1**

        ANTISENSE OLIGONUCLEOTIDES WHICH TARGET HUMAN ICAM-1

ISIS NO.	SEQ ID NO.	TARGET REGION	MODIFICATION
1558	1	AUG Codon (64-81)	P=O

3224	27	5'-CAP (32-51)	2'-O-methyl; P=S

Inhibition of ICAM-1 expression on the surface of interleukin-1ß-stimulated cells by the oligonucleotides or oligonucleotide analogs was determined by ELISA assay as described in Example 1. The oligonucleotides were tested in two different cell lines. None of the phosphodiester oligonucleotides inhibited ICAM-1 expression. This is probably due to the rapid degradation of phosphodiester oligonucleotides in cells. Of the five phosphorothioate oligonucleotides, the most active was ISIS 1570, which hybridizes to the AUG translation initiation codon.

Based on the initial data obtained with the five original targets, twelve more oligonucleotides (ISIS 1930,

- 28 -

1940 and 3067, see Table 1) were designed which would
hybridize with the ICAM-1 mRNA. The antisense
oligonucleotide (ISIS 3067) which hybridizes to the
predicted transcription initiation site (5' cap site) was
5   approximately as active in IL-1ß-stimulated cells as the
oligonucleotide that hybridizes to the AUG codon (ISIS
1570), as shown in Figure 8. ISIS 1931 and 1932 hybridize
5' and 3', respectively, to the AUG translation initiation
codon. All three oligonucleotides that hybridize to the
10 AUG region inhibit ICAM-1 expression, though ISIS 1932 was
slightly less active than ISIS 1570 and ISIS 1931.
Oligonucleotides which hybridize to the coding region of
ICAM-1 mRNA (ISIS 1933, 1934, 1935, 1574 and 1936)
exhibited weak activity. Oligonucleotides that hybridize
15 to the translation termination codon (ISIS 1937 and 1938)
exhibited moderate activity. Surprisingly, the most active
antisense oligonucleotide, ISIS 1939, targeted a specific
sequence in the 3'-untranslated region of the ICAM-1 mRNA.
The antisense activity demonstrated by ISIS 1939 was not
20 shared by other oligonucleotides (ISIS 1572, 1573, 1940)
which hybridize to 3'-untranslated sequences. In fact,
ISIS 1940, which targets the polyadenylation signal, failed
to inhibit ICAM-1 expression.

        Because ISIS 1939 proved unexpectedly to exhibit the
25 greatest antisense activity of the original 16
oligonucleotides tested, other oligonucleotides were
designed to hybridize to sequences in the 3'-untranslated
region of ICAM-1 mRNA (ISIS 2302, 2303, 2304, 2305, and
2307, as shown in Table 1). ISIS 2307, which hybridizes to
30 a site only five bases 3' to the ISIS 1939 target, was the
least active of the series (Figure 8). ISIS 2302, which
hybridizes to the ICAM-1 mRNA at a position 143 bases 3' to
the ISIS 1939 target, was the most active of the series,
with activity comparable to that of ISIS 1939. Examination
35 of the predicted RNA secondary structure of the human ICAM-
1 mRNA 3'-untranslated region (according to M. Zuker,
Science, 244:48-52, 1989) revealed that both ISIS 1939 and

ISIS 2302 hybridize to sequences predicted to be in a
stable stem-loop structure. Current dogma suggests that
regions of RNA secondary structure should be avoided when
designing antisense oligonucleotides. Thus, ISIS 1939 and
5 ISIS 2302 would not have been predicted to inhibit ICAM-1
expression.

Several antisense oligonucleotide analogs containing
modifications at the 2' position were also analyzed. The
2'-O-methyl phosphorothioate analog of ISIS 1570, ISIS
10 2974, was approximately threefold less effective than ISIS
1570 in inhibiting ICAM-1 expression in both HUVEC and A549
cells. In contrast, the 2'-O-methyl phosphorothioate
analog of ISIS 1939 and ISIS 2973, failed to inhibit ICAM-
1 expression in either cell line. Similar results were
15 obtained with 2'-fluoro analogs of ISIS 1570, ISIS 1939
(ISIS 2634 and 2637, respectively).

The control oligonucleotide ISIS 1821 did inhibit
ICAM-1 expression in HUVEC cells with activity comparable
to that of ISIS 1934; however, in A549 cells ISIS 1821 was
20 less effective than ISIS 1934. The negative control, ISIS
1821, was found to have a small amount of activity against
ICAM expression, probably due in part to its ability to
hybridize (12 of 13 base match) to the ICAM-1 mRNA at a
position 15 bases 3' to the AUG translation initiation
25 codon.

These studies indicate that the AUG translation
initiation codon and specific 3'-untranslated sequences in
the ICAM-1 mRNA were the most susceptible to antisense
oligonucleotide inhibition of ICAM-1 expression.

30 In addition to inhibiting ICAM-1 expression in human
umbilical vein cells and the human lung carcinoma cells
(A549), ISIS 1570, ISIS 1939 and ISIS 2302 were shown to
inhibit ICAM-1 expression in the human epidermal carcinoma
A431 cells and in primary human keratinocytes (shown in
35 Figure 9). These data demonstrate that antisense
oligonucleotides are capable of inhibiting ICAM-1
expression in several human cell lines. Furthermore, the

- 30 -

rank order potency of the oligonucleotides is the same in
the four cell lines examined. The fact that ICAM-1
expression could be inhibited in primary human
keratinocytes is important because epidermal keratinocytes
5   are an intended target of the antisense nucleotides.

EXAMPLE 6

Antisense oligonucleotide inhibition of ICAM-1
<u>expression in cells stimulated with other cytokines:</u>

Two oligonucleotides, ISIS 1570 and ISIS 1939, were
10   tested for their ability to inhibit TNF-α and IFN-γ-
induced ICAM-1 expression. Treatment of A549 cells with 1
uM antisense oligonucleotide inhibited IL-1ß, TNF-α and
IFN-γ-induced ICAM-1 expression in a sequence-specific
manner. The antisense oligonucleotides inhibited IL-1ß and
15   TNF-α-induced ICAM-1 expression to a similar extent, while
IFN-γ-induced ICAM-1 expression was more sensitive to
antisense inhibition. The control oligonucleotide, ISIS
1821, did not significantly inhibit IL-1ß- or TNF-α-induced
ICAM-1 expression and inhibited IFN-γ-induced ICAM-1
20   expression slightly, as follows:

Antisense Oligonucleotide
(% Control Expression)

<u>Cytokine</u>	<u>ISIS 1570</u>	<u>ISIS 1939</u>	<u>ISIS 1821</u>
3 U/ml IL-1β	56.6 ± 2.9	38.1 ± 3.2	95 ± 6.6
1 ng/ml TNF-α	58.1 ± 0.9	37.6 ± 4.1	103.5 ± 8.2
100 U/ml gamma-IFN	38.9 ± 3.0	18.3 ± 7.0	83.0 ± 3.5

EXAMPLE 7

<u>Antisense effects are abolished by sense strand controls:</u>

30   The antisense oligonucleotide inhibition of ICAM-1
expression by the oligonucleotides ISIS 1570 and ISIS 1939
could be reversed by hybridization of the oligonucleotides
with their respective sense strands. The phosphorothioate
sense strand for ISIS 1570 (ISIS 1575), when applied alone,
35   slightly enhanced IL-1ß-induced ICAM-1 expression.
Premixing ISIS 1570 with ISIS 1575 at equal molar

- 31 -

concentrations, prior to addition to the cells, blocked the effects of ISIS 1570. The complement to ISIS 1939 (ISIS 2115) enhanced ICAM-1 expression by 46% when added to the cells alone. Prehybridization of ISIS 2115 to ISIS 1939

5   completely blocked the inhibition of ICAM-1 expression by ISIS 1939.

EXAMPLE 8

Measurement of oligonucleotide Tm (dissociation
<u>temperature of oligonucleotide from target):</u>

10   To determine if the potency of the inhibition of ICAM-1 expression by antisense oligonucleotides was due to their affinity for their target sites, thermodynamic measurements were made for each of the oligonucleotides. The antisense oligonucleotides (synthesized as

15   phosphorothioates) were hybridized to their complementary DNA sequences (synthesized as phosphodiesters). Absorbance vs. temperature profiles were measured at 4 μM each strand oligonucleotide in 100 mM Na+, 10 mM phosphate, 0.1 mM EDTA, pH 7.0. Tm's and free energies of duplex formation

20   were obtained from fits of data to a two-state model with linear sloping baselines (Petersheim, M. and D.H. Turner (1983) *Biochemistry*, 22: 256-263). Results are averages of at least three experiments.

       When the antisense oligonucleotides were

25   hybridized to their complementary DNA sequences (synthesized as phosphodiesters), all of the antisense oligonucleotides with the exception of ISIS 1940 exhibited a Tm of at least 50°C. All the oligonucleotides should therefore be capable of hybridizing to the target ICAM-1

30   mRNA if the target sequences were exposed. Surprisingly, the potency of the antisense oligonucleotide did not correlate directly with either Tm or $\Delta G°_{37}$. The oligonucleotide with the greatest biological activity, ISIS 1939, exhibited a Tm which was lower than that of the

35   majority of the other oligonucleotides. Thus, hybridization affinity is not sufficient to ensure biological activity.

EXAMPLE 9

Effect of oligonucleotide length on
<u>antisense inhibition of ICAM-1 expression:</u>

        The effect of oligonucleotide length on antisense

5 activity was tested using truncated versions of ISIS 1570
(ISIS 2165, 2173, 2149, 2163 and 2164) and ISIS 1939 (ISIS
2540, 2544, 2545, 2546, 2547 and 2548). In general,
antisense activity decreased as the length of the
oligonucleotides decreased. Oligonucleotides 16 bases in

10 length exhibited activity slightly less than 18 base
oligonucleotides. Oligonucleotides 14 bases in length
exhibited significantly less activity, and oligonucleotides
12 or 10 bases in length exhibited only weak activity.
Examination of the relationship between oligonucleotide

15 length and Tm and antisense activity reveals that a sharp
transition occurs between 14 and 16 bases in length, while
Tm increases linearly with length (Figure 10).

EXAMPLE 10

<u>Specificity of antisense inhibition of ICAM-1:</u>

20   The specificity of the antisense oligonucleotides
ISIS 1570 and ISIS 1939 for ICAM-1 was evaluated by
immunoprecipitation of ^{35}S-labelled proteins. A549 cells
were grown to confluence in 25 cm^2 tissue culture flasks and
treated with antisense oligonucleotides as described in

25 Example 4. The cells were stimulated with interleukin-1ß
for 14 hours, washed with methionine-free DMEM plus 10%
dialyzed fetal calf serum, and incubated for 1 hour in
methionine-free medium containing 10% dialyzed fetal calf
serum, 1 μM oligonucleotide and interleukin-1ß as

30 indicated. ^{35}S-Methionine/cysteine mixture (Tran^{35}S-label,
purchased from ICN, Costa Mesa, CA) was added to the cells
to an activity of 100 μCi/ml and the cells were incubated
an additional 2 hours. Cellular proteins were extracted by
incubation with 50 mM Tris-HCl pH 8.0, 150 mM NaCl, 1.0%

35 NP-40, 0.5% deoxycholate and 2mM EDTA (0.5 ml per well) at
4°C for 30 minutes. The extracts were clarified by
centrifugation at 18,000 x g for 20 minutes. The
supernatants were preadsorbed with 200 μl protein G-

Sepharose beads (Bethesda Research Labs, Bethesda MD) for 2
hours at 4°C, divided equally and incubated with either 5
µg ICAM-1 monoclonal antibody (purchased from AMAC Inc.,
Westbrook ME) or HLA-A,B antibody (W6/32, produced by
5   murine hybridoma cells obtained from the American Type
Culture Collection, Bethesda, MD) for 15 hours at 4°C.
Immune complexes were trapped by incubation with 200 µl of
a 50% suspension of protein G-Sepharose (v/v) for 2 hours
at 4°C, washed 5 times with lysis buffer and resolved on an
10   SDS-polyacrylamide gel. Proteins were detected by
autoradiography.
        Treatment of A549 cells with 5 units/ml of
interleukin-1ß was shown to result in the synthesis of a
95-100 kDa protein migrating as a doublet which was
15   immunoprecipitated with the monoclonal antibody to ICAM-1.
The appearance as a doublet is believed to be due to
differently glycosylated forms of ICAM-1. Pretreatment of
the cells with the antisense oligonucleotide ISIS 1570 at a
concentration of 1 µM decreased the synthesis of ICAM-1 by
20   approximately 50%, while 1 µM ISIS 1939 decreased ICAM-1
synthesis to near background. Antisense oligonucleotide
ISIS 1940, inactive in the ICAM-1 ELISA assay (Examples 1
and 5) did not significantly reduce ICAM-1 synthesis. None
of the antisense oligonucleotides hybridizable with ICAM-1
25   targets had a demonstrable effect on HLA-A, B synthesis,
demonstrating the specificity of the oligonucleotides for
ICAM-1. Furthermore, the proteins which nonspecifically
precipitated with the ICAM-1 antibody and protein G-
Sepharose were not significantly affected by treatment with
30   the antisense oligonucleotides.

EXAMPLE 11
Screening of additional antisense oligonucleotides and
<u>analogs for activity against ICAM-1 by cell adhesion assay:</u>
        Human umbilical vein endothelial (HUVEC) cells
35   were grown and treated with oligonucleotides as in Example
4. Cells were treated with either antisense
oligonucleotide ISIS 1939, the inactive antisense
oligonucleotide ISIS 1940, or the control oligonucleotide

- 34 -

ISIS 1821 for 4 hours, then stimulated with TNF-α for 20
hours. Basal HUVEC minimally bound HL-60 cells, while TNF-
stimulated HUVEC bound 19% of the total cells added.
Pretreatment of the HUVEC monolayer with 0.3 μM ISIS 1939
5   reduced the adherence of HL-60 cells to basal levels, as
shown in Figure 11. The control oligonucleotide, ISIS 1821
and the inactive oligonucleotide ISIS 1940 reduced the
percentage of cells adhering from 19% to 9%. These data
indicate that antisense oligonucleotides targeting ICAM-1
10 may specifically decrease adherence of a leukocyte-like
cell line (HL-60) to TNF-α-treated HUVEC.
EXAMPLE 12
ELISA screening of additional antisense
oligonucleotides and oligonucleotide analogs
15 for activity against ELAM-1 gene expression:
        Primary human umbilical vein endothelial (HUVEC)
cells, passage 2 to 5, were plated in 96-well plates and
allowed to reach confluence. Cells were washed three times
with Opti-MEM (GIBCO, Grand Island NY). Cells were treated
20 with increasing concentrations of oligonucleotide diluted
in Opti-MEM containing 10 μg/ml DOTMA solution (Bethesda
Research Labs, Bethesda MD) for 4 hours at 37°C. The medium
was removed and replaced with EGM-UV (Clonetics, San Diego
CA) plus oligonucleotide. Tumor necrosis factor α was
25 added to the medium (2.5 ng/ml) and the cells were
incubated an additional 4 hours at 37°C.
        ELAM-1 expression was determined by ELISA. Cells
were gently washed three times with Dulbecco's phosphate-
buffered saline (D-PBS) prewarmed to 37°C. Cells were
30 fixed with 95% ethanol at 4°C for 20 minutes, washed three
times with D-PBS and blocked with 2% BSA in D-PBS. Cells
were incubated with ELAM-1 monoclonal antibody BBA-1 (R&D
Systems, Minneapolis MN) diluted to 0.5 μg/ml in D-PBS
containing 2% BSA for 1 hour at 37°C. Cells were washed
35 three times with D-PBS and the bound ELAM-1 antibody
detected with biotinylated goat anti-mouse secondary
antibody followed by ß-galactosidase-conjugated
streptavidin as described in Example 1.

- 35 -

The activity of antisense phosphorothioate
oligonucleotide analogs which target 11 different regions
on the ELAM-1 cDNA and two oligonucleotides which target
ICAM-1 (as controls) was determined using the ELAM-1 ELISA.
5 The oligonucleotide analogs and targets are shown in Table
2.

TABLE 2

ANTISENSE OLIGONUCLEOTIDES WHICH TARGET HUMAN ELAM-1

ISIS NO.	SEQ ID NO.	TARGET REGION	MODIFICATION
10 1926	28	AUG Codon (143-164)	P=S
2670	29	3'-Untranslated (3718-3737)	P=S
2673	30	3'-Untranslated (2657-2677)	P=S
2674	31	3'-Untranslated (2617-2637)	P=S
2678	32	3'-Untranslated (3558-3577)	P=S
15 2679	33	5'-Untranslated (41-60)	P=S
2680	34	3'-Untranslated (3715-3729)	P=S
2683	35	AUG Codon (143-163)	P=S
2686	36	AUG Codon (149-169)	P=S
2687	37	5'-Untranslated (18-37)	P=S
20 2693	38	3'-Untranslated (2760-2788)	P=S
2694	39	3'-Untranslated (2934-2954)	P=S

In contrast to what was observed with antisense
oligonucleotides targeted to ICAM-1 (Example 5), the most
potent oligonucleotide modulator of ELAM-1 activity (ISIS
25 2679) was hybridizable with specific sequences in the 5'-
untranslated region of ELAM-1. ISIS 2687, an
oligonucleotide which hybridized to sequences ending three
bases upstream of the ISIS 2679 target, did not show
significant activity (Figure 12). Therefore, ISIS 2679
30 hybridizes to a unique site on the ELAM-1 mRNA, which is
uniquely sensitive to inhibition with antisense

- 36 -

oligonucleotides. The sensitivity of this site to
inhibition with antisense oligonucleotides was not
predictable based upon RNA secondary structure predictions
or information in the literature. Oligonucleotides which
are hybridizable with the ELAM-1 AUG codon (ISIS 2683 and
ISIS 2686) exhibit moderate activity (Figure 12).

CLAIMS

What is claimed is:

      1.   An oligonucleotide or oligonucleotide analog specifically hybridizable with at least a portion of a nucleic acid encoding a protein capable of modulating cell adhesion.

      2.   The oligonucleotide or oligonucleotide analog of claim 1 which is specifically hybridizable with mRNA.

      3.   The oligonucleotide or oligonucleotide analog of claim 1 which is specifically hybridizable with a gene, forming a triple stranded structure for modulating the amount of mRNA made from said gene.

      4.   The oligonucleotide or oligonucleotide analog of claim 2 specifically hybridizable with a transcription initiation site, a translation initiation site, 5'-untranslated sequence, 3'-untranslated sequence, an intron/exon junction or an intervening sequence of mRNA.

      5.   The oligonucleotide or oligonucleotide analog of claim 4 specifically hybridizable with a 5' cap site or an adjacent sequence.

      6.   The oligonucleotide or oligonucleotide analog of claim 1 wherein said protein is intercellular adhesion molecule-1.

      7.   The oligonucleotide or oligonucleotide analog of claim 1 wherein said protein is endothelial leukocyte adhesion molecule-1.

      8.   The oligonucleotide or oligonucleotide analog of claim 1 wherein said protein is vascular cell adhesion molecule-1.

      9.   The oligonucleotide or oligonucleotide analog of claim 1 comprising from about 3 to about 50 subunits.

      10.   The oligonucleotide or oligonucleotide analog of claim 1 comprising from about 8 to about 25 subunits.

- 53 -

11. The oligonucleotide or oligonucleotide
analog of claim 1 comprising from about 10 to about 20
subunits.

12. The oligonucleotide or oligonucleotide
5 analog of claim 1 in a pharmaceutically acceptable carrier.

13. The oligonucleotide or oligonucleotide
analog of claim 1 which is 2'-O-methyl, 2'-fluoro,
phosphorothioate, 2'-O-methyl phosphorothioate, or 2'-
fluoro phosphorothioate.

14. An oligonucleotide or oligonucleotide analog
comprising one of the sequences identified in Table 1 or
Table 2.

15. The oligonucleotide or oligonucleotide
analog of claim 14 in a pharmaceutically acceptable
carrier.

16. The oligonucleotide or oligonucleotide
analog of claim 14 which is 2'-O-methyl, 2'-fluoro,
phosphorothioate, 2'-O-methyl phosphorothioate, or 2'-
fluoro phosphorothioate.

17. A method of modulating the synthesis of
intercellular adhesion molecules in an animal comprising
contacting the animal with an oligonucleotide or
oligonucleotide analog specifically hybridizable with at
least a portion of a nucleic acid encoding a protein
capable of modulating cell adhesion.

18. The method of claim 17 wherein the
oligonucleotide or oligonucleotide analog is specifically
hybridizable with mRNA.

19. The method of claim 17 wherein the
oligonucleotide or oligonucleotide analog is specifically
hybridizable with a gene, forming a triple stranded
structure for modulating the amount of mRNA made from said
gene.

20. The method of claim 17 wherein the
oligonucleotide or oligonucleotide analog is specifically
hybridizable with a transcription initiation site, a
translation initiation site, 5'-untranslated sequence, 3'

untranslated sequence, an intron/exon junction or an intervening sequence of mRNA.

21. The method of claim 17 wherein said oligonucleotide or oligonucleotide analog is specifically hybridizable with a 5' cap site of mRNA or an adjacent sequence.

22. The method of claim 17 wherein said protein is intercellular adhesion molecule-1.

23. The method of claim 17 wherein said protein is endothelial leukocyte adhesion molecule-1.

24. The method of claim 17 wherein said protein is vascular cell adhesion molecule-1.

25. The method of claim 17 wherein the oligonucleotide or oligonucleotide analog comprises a sequence identified in Table 1 or Table 2.

26. The method of claim 17 wherein said oligonucleotide or oligonucleotide analog is 2'-O-methyl, 2'-fluoro, phosphorothioate, 2'-O-methyl phosphorothioate, or 2'-fluoro phosphorothioate.

27. A method of treating an animal suspected of having a disease which is modulated by changes in intercellular adhesion molecules comprising contacting the animal with an oligonucleotide or oligonucleotide analog
5 specifically hybridizable with nucleic acids encoding at least a portion of a protein which modulates the synthesis or metabolism of intercellular adhesion molecules.

28. The method of claim 27 wherein said oligonucleotide or oligonucleotide analog is specifically hybridizable to a transcription initiation site, translation initiation site, 5'-untranslated sequences, 3' untranslated sequences or an intervening sequence of mRNA.

29. The method of claim 27 wherein said oligonucleotide or oligonucleotide analog is specifically hybridizable with a 5' cap site of mRNA and adjacent sequences.

30. The method of claim 27 wherein said protein is intercellular adhesion molecule-1.

31.   The method of claim 27 wherein said protein is endothelial leukocyte adhesion molecule-1.

32.   The method of claim 27 wherein said protein is vascular cell adhesion molecule-1.

33.   The method of claim 27 wherein the oligonucleotide or oligonucleotide analog is in a pharmaceutically acceptable carrier.

34.   The method of claim 27 wherein the oligonucleotide or oligonucleotide analog comprises one of the sequences identified in Table 1 or Table 2.

35.   The method of claim 27 wherein said
5   oligonucleotide or oligonucleotide analog is 2'-O-methyl, 2'-fluoro, phosphorothioate, 2'-O-methyl phosphorothioate, or 2'-fluoro phosphorothioate.

INTERNATIONAL SEARCH REPORT

I. CLASSIFICATION OF SUBJECT MATTER (if several classification symbols apply, indicate all) 6

According to International Patent Classification (IPC) or to both National Classification and IPC

US: 514/44; 536/27

IPC(5): A61K 31/70; C07H 17/00

II FIELDS SEARCHED

Minimum Documentation Searched 7	
Classification System	Classification Symbols
US	514/44; 536/27

Documentation Searched other than Minimum Documentation
to the Extent that such Documents are Included in the Fields Searched 8

APS, GENBANK, UEMBL, CAS

III. DOCUMENTS CONSIDERED TO BE RELEVANT 9

Category *	Citation of Document, 11 with indication, where appropriate, of the relevant passages 12	Relevant to Claim No. 13
Y	Pharmaceutical Research. Volume 5. No. 9 issued 1988. Zon. "Oligonucleotide Analogues as Potential Chemotherapeutic Agents". pages 539-549. see entire document.	1-5,9-12 26-29.33-35
Y	Cell. Volume 52. issued 25 March 1988. D.E. Stauton et al., "Primary Structure of ICAM-1 demonstrates Interaction between members of the Immunoglobulin and Integrin Supergene Families". pages 925-933. see entire documents.	6.22.30

* Special categories of cited documents: 10

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

IV. CERTIFICATION

Date of the Actual Completion of the International Search	Date of Mailing of this International Search Report
07 OCTOBER 1991	28 OCT 1991
International Searching Authority	Signature of Authorized Officer
ISA/US	SUZANNE ZISKA

FURTHER INFORMATION CONTINUED FROM THE SECOND SHEET

V. ☐ OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE [1]

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. ☐ Claim numbers   . because they relate to subject matter [12] not required to be searched by this Authority, namely:

2. ☐ Claim numbers   , because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out [13], specifically:

3. ☐ Claim numbers_____, because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. ☒ OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING [2]

This International Searching Authority found multiple inventions in this international application as follows:

Group I, claims 1-16 and 17-26
Group II claims 27-35

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. ☐ As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

☐ The additional search fees were accompanied by applicant's protest.

☒ No protest accompanied the payment of additional search fees.

Form PCT/ISA/210 (supplemental sheet (2) (Rev. 11-87)
